

CUSTOMER STORY

Kojima Industries 3D prints its own robot hands: part cost down 67%, lead time from 14 days to 1

Printed in-house on Markforged, the robot hands got lighter, so the robots no longer had to be oversized to carry them—and overall equipment investment came down with them.

COMPANY & CHALLENGE

01 Background

An 88-year-old parts maker, and a step still done by hand

Kojima, now in its 88th year, has more than 8,000 employees across its group companies and operations in Japan, the United States, Thailand, China and Europe. It designs and produces automotive interior, engine and exterior components, and uses its group supply chain to offer one-stop service from development through high-volume production.

Electrification and system integration are reshaping the automotive industry, and globalization has sharpened competition among parts suppliers. Kojima works to the QCD principle—Quality, Cost, Delivery—in pursuit of manufacturing that is more precise, faster and less expensive.

One production step required operators to attach non-woven fabric seals by hand. As the number of seals grew, the step took more and more time. To reduce labor, Kojima set out to automate it with robots.

THE PROBLEM

02 The problem

A heavy hand calls for a bigger robot

The robot hands on the automation equipment were originally made of metal. A robot hand sits at the end of the arm, and its weight counts directly against the load the robot has to carry.

The weight of the metal hands pushed the robots into configurations larger than the task itself required, and overall equipment cost rose significantly. In other words, the weight of the hand was not just a property of the hand—it decided which class of robot had to be bought.

The cost was not only in the hand, but in the bigger robot it took to carry it.

How hand weight travels to the equipment budget

Before	Metal hand	→	Weight counts against robot load	→ Robot sized beyond the task	→ **Equipment cost rises**
With 3D printing	Printed hand	→	Lighter, same strength	→ No robot upsizing	→ Equipment investment down

Summarized from the Markforged customer story; the story does not disclose weight saved or robot models.

THE APPROACH

03 The approach

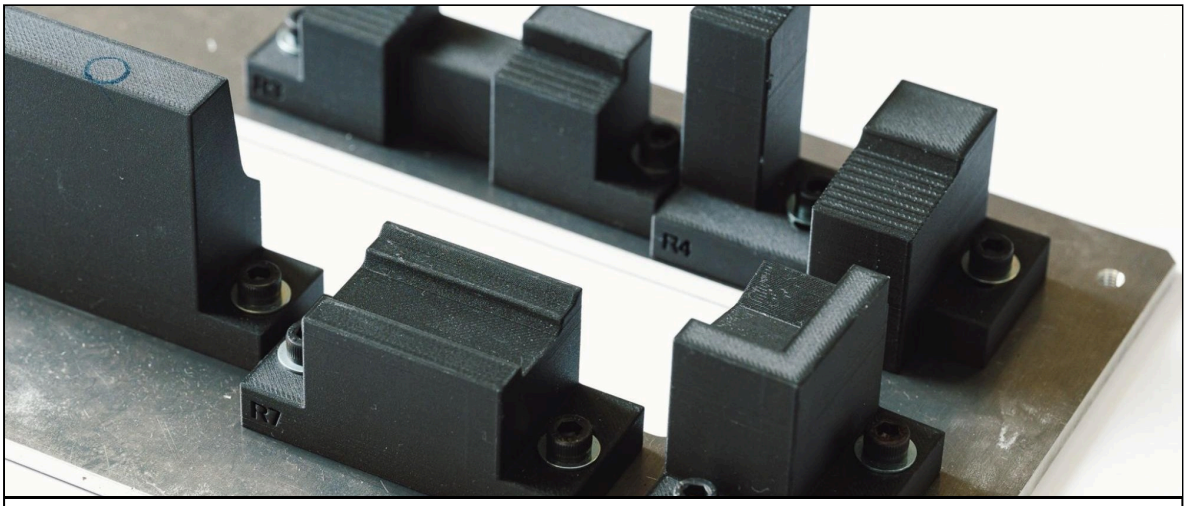

Print the hands in-house

Kojima adopted Markforged 3D printers—the customer story lists the Mark Two and the X7—to produce its robot hands.

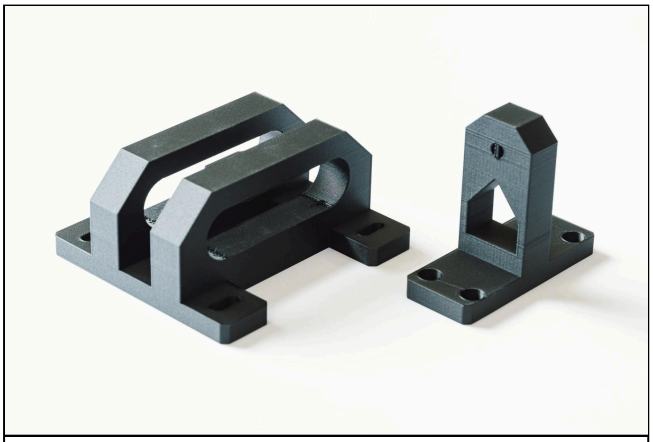

According to the customer story, switching from metal to 3D-printed components cut the weight of the robot hands significantly while keeping the strength required for production use. The robots no longer needed oversized configurations, and equipment investment came down.

The story also shows several printed parts in use on the line: a cylinder joint that lets a cylinder adjust the angle of a jig base, a fixture that locates and holds the product during the process, and a stand that stores rolls of seal stickers.

Three printed parts shown in the story

P-02 **Jig Fixture** Locates and holds the product during the process.

P-01

Cylinder Joint

Lets a cylinder adjust the angle of the jig base.

P-03

Sticker Storage

Stores rolls of seal stickers.

RESULTS

04 Results

67%, 14 days to 1, and one less 2D drawing

QCD scorecard

Q Quality	C Cost	D Delivery	+ Design work
Same strength	**–67%**	**14→1 day**	**~ –30%**
production strength kept	robot hand part cost	outsourced vs. in-house	certain parts; no 2D drawings

Part lead time

Outsourced machining

14 days

Printed in-house on Markforged

1 day

Robot hand part cost

Machined parts

100

3D-printed parts

33

index, machined parts = 100 (–67%)

Where the figures come from: all three are taken from the Markforged customer story; 14 days vs. 1 day is from the lead time comparison in the story PDF. The cost index is derived from the stated 67% reduction.

Before and after

	Before	With 3D printing
Production method	Metal, machined	**Markforged 3D printing**
Where it is made	Outsourced machining	**In-house**
What it takes to start	Detailed 2D drawings before ordering	**3D CAD data is enough**
Hand weight	Heavy, counts against robot load	**Much lighter, production strength kept**
Robot configuration	Sized beyond the task	**No upsizing needed**

Cost. The 3D-printed robot hand components cost 67% less to produce than conventionally machined parts.

Lead time. The customer story compares 14 days for outsourced part production with 1 day for printing in-house on Markforged. Against outsourced machined parts, both cost and lead time came down sharply.

Design work. Outsourced machining required detailed 2D drawings before an order could be placed; 3D printing starts directly from 3D CAD data. Depending on the part, design labor fell by approximately 30%.

Of the three figures, the last is the easiest to overlook. A 2D machining drawing never ends up on the equipment, but outsourced machining cannot start without one. Printing in-house removes that step.

TAKEAWAY

05 Takeaway

Look at the hand before sizing the robot

For parts makers automating manual steps, Kojima's experience suggests an order of checks: the weight of the robot hand determines the robot configuration, and the robot configuration determines equipment investment. If the hand can be made lighter and faster in-house, the cost and schedule of the whole automation project gain a variable that can be adjusted.

What Kojima prints is not the product it sells but the tools on its line—robot hands, fixtures, storage stands. These parts are usually designed around one specific process and made in small numbers, which is exactly where outsourcing costs and waiting time show most; all three figures in this case fall in that segment.

About Kojima Industries

Kojima Industries Corporation (Kojima Press Industry Co., Ltd.) is a major Japanese automotive parts manufacturer in its 88th year, with more than 8,000 employees across its group companies and operations in Japan, the United States, Thailand, China and Europe, offering one-stop service from development through production.

About Markforged

Markforged, Inc. supplies industrial additive manufacturing systems, enabling manufacturing and sustainment organisations to produce functional parts, tooling and spares at the point of use through continuous fibre composite and metal solutions.
